Name of the Project: SENV

One paragraph description of the project:

SENV is a modular runtime security gateway designed to protect enterprise AI agent workflows from indirect prompt injection, privileged tool misuse, and data exfiltration without altering underlying foundation models. Sitting as a protective middleware between autonomous agents and enterprise execution environments (databases, APIs, and file systems), ***SENV*** intercepts privileged actions before execution. It evaluates proposed tool calls through deterministic capability policies and dual-execution behavioral validation to detect state hijacking and context poisoning in real time. By pairing runtime interception with an automated, graph-based adversarial red-teaming engine, the platform establishes provable runtime safety boundaries for multi-agent enterprise deployments.

Supervisor & Innovation Expert:

Supervisor: Prof. Mohammad Mahmoody

Innovation Expert: Erhan Dolak
